(54) Title: **METHOD AND APPARATUS FOR THE SYNCHRONIZATION OF MULTIPLE CABLE MODEM TERMINATION SYSTEM DEVICES**

(57) Abstract: A plurality of CMTS devices are linked together and synchronized to facilitate communication between the respective CMTS devices and respective downstream cable modems. According to one embodiment of the invention, one of the CMTS devices is designated as a master device, and the other CMTS devices are designated as slave devices. The respective CMTS devices are connected to each other by means of a synchronization bus. The master CMTS device then generates and broadcasts a future time stamp value, which is received by the respective slave CMTS devices. When the time stamp counter in the master CMTS device reaches the transmitted value, a control signal is broadcast over the synchronization bus. The slave CMTS devices then retrieve the time stamp value and reset their respective local time stamp counters to the received value. In this manner, the CMTS devices are synchronized.

1 METHOD AND APPARATUS FOR THE SYNCHRONIZATION OF MULTIPLE CABLE
MODEM TERMINATION SYSTEM DEVICES

5 FIELD OF THE INVENTION

The present invention relates generally to communication systems. The present invention more particularly relates to a cable modem system wherein information is communicated between a plurality of cable modems and a cable modem termination system that includes a plurality of cable modem termination system devices.

10 BACKGROUND OF THE INVENTION

The desired solution for high speed data communications appears to be cable modem. Cable modem is capable of providing high data throughput rates, and is thus suitable for high speed file transfer, video teleconferencing and pay-per-view television. Further, cable modems may simultaneously provide high speed Internet access, digital television (such as pay-per-view) and digital telephony.

15 Although cable modems are used in a shared access system, wherein a plurality of subscribers compete for bandwidth over a common coaxial cable, any undesirable reduction in actual data rate is easily controlled simply by limiting the number of shared users on each system. In this manner, each user is assured of a sufficient data rate to provide uninterrupted video teleconferencing or pay-per-view television, for example.

20 Cable modem systems typically include one or more head ends or cable modem termination system (CMTS) devices that engage in bidirectional communication with the various subscribers' cable modems. Both the cable modems and the CMTS devices include modulators to transmit data (either upstream from the cable modems to the CMTS devices, or downstream from the CMTS devices to the cable modems), as well as demodulators to receive and demodulate the incoming data. Such system are preferably flexible to accommodate varying numbers of subscribers (typically an ever-increasing number).

25 MAP information is transmitted on one or more downstream channels by the cable modem termination system to all of the cable modems on a given frequency channel. As is well known in the art, MAP information covers all time periods on an upstream channel. MAP information typically consists of the combination of one or more of the following: request regions (i.e., the contention area that a modem can request new band width), request/data regions (where both data and request can be transmitted), initial maintenance regions (where new modems have the right to try and sign on), station maintenance regions (for modems that are in operation), and short and long data grant regions (for transmitting data). The short and long data grants may either be based on a request or can also be unsolicited grants. The MAP will consist of a combination of these regions, all as decided by the MAP generator.

30
35

SUMMARY OF THE INVENTION

The present invention specifically addresses and alleviates certain deficiencies associated with the above-mentioned prior art.

According to an aspect of the invention, a plurality of CMTS devices are linked together to form a larger medium access control (MAC) domain. The CMTS devices are preferably synchronized to facilitate communication between the CMTS devices and the cable modems.

In another embodiment of the invention, MAP information is transmitted to one or more of the CMTS devices, with such MAP information then being passed on to the downstream cable modems. The MAP information is then transmitted to the rest of the CMTS devices of the system. Each of the upstream channels is uniquely identified so that each of the CMTS devices extracts only the relevant MAP information from the broadcasted information.

Thus, in one illustrative embodiment of the invention, a plurality of CMTS devices are linked together and synchronized to facilitate communication between the respective CMTS devices and the downstream cable modems. According to the invention, one of the CMTS devices is designated as a master device, and the other CMTS devices are designated as slave devices. The respective CMTS devices are connected to each other by means of a synchronization bus. A future time stamp value is generated based on the counter value of the master CMTS device, and the future time stamp value is broadcast over the bus and is received by the respective CMTS devices. When the time stamp counter in the master CMTS device reaches the generated future time stamp value, a control signal from the master CMTS device is broadcast over the synchronization bus. The slave CMTS devices then retrieve the future time stamp value and reset their respective local time stamp counters to the future time stamp value. In this manner, the CMTS devices are synchronized.

In another illustrative embodiment, MAP information is generated and transmitted to at least one CMTS device, which forwards it on to the cable modems. The MAP information is then transmitted to the other CMTS devices. Each CMTS device receives the MAP information and filters out the information that is irrelevant to that particular CMTS device. Each CMTS device determines the relevant information based on unique identifiers assigned to the respective upstream channels, which are included in the MAP information.

BRIEF DESCRIPTION OF THE DRAWINGS

These and other features, aspects and advantages of the present invention will be more fully understood when considered with respect to the following detailed description, appended claims and accompanying drawings wherein:

FIG. 1 is a schematic diagram of a hybrid fiber coaxial (HFC) network showing typical pathways for data transmission between a headend (which contains the cable modem termination system) and a plurality of homes (each of which contains a cable modem):

FIG. 2 is a simplified block diagram of a cable modem system wherein a line card which defines a cable modem termination system (CMTS) is disposed at the headend and a cable

1 modem is disposed within a representative home:

FIG. 3 is a schematic diagram of a system incorporating multiple CMTS devices according to one illustrative embodiment of the invention:

5 FIG. 4 is a flow chart depicting the operational flow of one illustrative embodiment of the system of FIG. 3:

FIG. 5 is a flow chart depicting the operational flow of another illustrative embodiment of the invention:

FIG. 6 is a schematic diagram of one illustrative embodiment of a circuit used for time-stamp generation and time stamp synchronization according to the present invention:

10 FIG. 7 is a block diagram of a CMTS device circuit incorporating the circuit shown in FIG. 6; and

FIG. 8 is a timing diagram showing the relationships between various signals transmitted according to one illustrative embodiment of the invention.

15 DETAILED DESCRIPTION OF THE INVENTION

Referring now to FIGS. 1 and 2, an overall cable modem system 1000, such as the one disclosed in pending United States regular Application No. 09/574,558, filed on May 19, 2000, and hereby expressly incorporated by reference, is shown in detail. Briefly, the system 1000 includes one or more headends 1012 including respective cable modem termination systems (CMTS) 1042 (FIG. 2) that are located at a cable company facility and that function as modems to service a large number of subscribers. Each subscriber has a cable modem (CM) 12. Thus, the cable modem termination systems 1042 are capable of facilitating bidirectional communication with any desired one of the plurality of cable modems 12.

25 As used herein, the cable modem termination system (CMTS) 1042 is defined to include that portion of a headend which facilitates communication with a plurality of cable modems 12. A typical cable modem termination system includes one or more burst receivers, a continuous transmitters, and medium access controls (MAC).

30 In one embodiment, the cable modem termination system 1042 communicates with the plurality of cable modems 12 via a hybrid fiber coaxial (HFC) network 1010, wherein optical fiber 1020 provides communication to a plurality of fiber nodes or hubs 1022, and each fiber node typically serves approximately 500 to 2,000 subscribers. The subscribers communicate with the fiber node via a common (or shared) coaxial cable 1028. It is this sharing of the common coaxial cable which necessitates that the number of cable modems 12 attached thereto be limited so as to mitigate the likelihood of undesirable bit rate reductions which inherently occur when an excessive number of cable modems 12 communicate simultaneously over a single coaxial cable 1028.

35 The hybrid fiber coaxial network 1010 of a cable modem system 1000 utilizes a point-to-multipoint topology to facilitate communication between each cable modem termination system 1042 and the corresponding cable modems 12. Frequency domain multiple access (FDMA) is

1 preferably used to facilitate communication from the cable modem termination system 1042 to
each of the cable modems 12, i.e., in the downstream direction. Frequency domain multiple
access (FDMA)/time domain multiple access (TDMA) is preferably used to facilitate
communication from each cable modem 12 to the cable modem termination system 1042, i.e.,
5 in the upstream direction.

Each cable modem termination system (CMTS) 1042 includes at least one downstream
modulator for facilitating the transmission of data communications from the CMTS 1042 to the
cable modems 12. In addition, each CMTS 1042 includes at least one upstream demodulator for
facilitating the reception of data communications from the respective cable modems 12. The
10 downstream modulator(s) preferably utilize a data transmission protocol that provides a relatively
high throughput rate, while the upstream demodulators may utilize
a data transmission protocol that provides a lower throughput rate.

Similarly, each cable modem 12 includes an upstream modulator for facilitating the
transmission of data to the corresponding cable modem termination system 1042 and a
15 downstream demodulator for receiving data from the cable modem termination system 1042.

Contemporary cable modem systems operate on a plurality of upstream channels and
preferably utilize time division multiple access (TDMA) in order to facilitate communication
between a plurality of cable modems 12 and a single cable modem termination system 1042 on
each upstream channel. Typically, between 250 and 500 cable modems communicate with a
20 single cable modem termination system on a given upstream channel.

In order to accomplish TDMA for upstream communication, it is necessary to assign time
slots within which the respective cable modems 12 are allowed to transmit. Assignment of those
time slots results in the generation of MAP information, as described above. The MAP
information is forwarded on to the cable modems 12, which are controlled by that MAP
25 information, as is described in more detail below.

Referring now to FIG. 3, a system 20 depicting one illustrative embodiment of the
invention is shown. System 20 provides a modular system that can accommodate the diverse
needs of cable operators in different geographic regions. System 20 includes a plurality of CMTS
devices, including one master CMTS device 22 and one or more slave CMTS devices 24. It will
30 be understood that the number of slave CMTS devices 24 will vary depending on the
requirements of a particular geographic region. Moreover, as the requirements for a particular
region change (e.g., as the number of subscribers grows in a particular region), additional slave
CMTS devices 24 may be incorporated into the system 20. Thus, system 20 is readily
expandable.

35 The master CMTS device 22 includes a downstream channel 26 to transmit data to the
downstream cable modems 12 being serviced by the master device 22. In addition, each CMTS
device 22 and 24 includes at least one upstream channel 28, and preferably plural such channels,
to receive data transmitted by the respective cable modems. One or more of the slave CMTS
devices 24 may also include a downstream channel 26 (shown in dashed lines in FIG. 3).

1 The master CMTS device 22 is connected to each of the slave CMTS devices 24 by means of a synchronization bus 30. As is described in greater detail below, master CMTS device 22 is programmed to broadcast certain information over bus 30 for receipt by the respective slave CMTS devices 24 to control the respective slave CMTS devices. In addition, time stamp
5 information for synchronizing the CMTS devices 22 and 24 is broadcast over bus 30 for receipt by all of the CMTS devices 22 and 24.

 As used herein, the term "synchronization bus" is intended to refer to any path to allow the transmission of data, for example, a peripheral component interface ("PCI"), back-plane bus, four-wire interface, coaxial cable, or even a wireless path. Thus, the term "synchronization bus"
10 is not intended to refer to any particular type of path; rather, it is used herein to refer to any suitable path for the transmission of the below-described data.

 Referring now to FIG. 4, the operational flow of system 20 in carrying out a synchronization routine is described in more detail. Operation begins at step 50, with system 20 generating a future time stamp value. In one embodiment, system 20 polls the master CMTS
15 device 22 for its current counter value, and generates a future time stamp value based on that current counter value. The future time stamp value is a value that will be used to synchronize the counter of each CMTS device 22 and 24. At step 52, system 20 broadcasts the future time stamp value over bus 30, along with appropriate control data for receipt by the respective devices 22 and 24. Preferably, the future time stamp value is a 32-bit data word, and the control data
20 precedes the data word and serves to identify the data as corresponding to a future time stamp value.

 Then, operation proceeds to step 54, and the respective CMTS devices 22 and 24 receive the broadcasted data. CMTS devices 22 and 24 process the control data to determine that the data packet contains a future time stamp value, and the respective CMTS devices 22 and 24 then
25 store the future time stamp value to an appropriate register. As is described in detail below, in one illustrative embodiment master CMTS device 22 stores the future value in a comparison register, while the slave devices 24 store the value in respective load registers.

 In one embodiment, system 20 uses conventional software interrupts or polling mechanisms to detect missing time stamp transmissions at the respective CMTS devices 22 and
30 24. For example, software interrupts may operate to check the respective CMTS devices 22 and 24 to ensure that each transmission was received. In one embodiment, this is accomplished by a software interrupt that reads the value of the TGCVerify register 306 for each CMTS device 22 and 24.

 At query block 56, master CMTS device 22 determines whether its internal time stamp
35 counter has reached the value of the future time stamp. In one embodiment, device 22 compares the value of its time stamp counter with the future time stamp value stored in its comparison register. Operation remains at query block 56 until master CMTS device 22 determines that in fact its internal counter has reached the transmitted future time stamp value. Operation then proceeds to step 58, and master CMTS device 22 broadcasts a corresponding control signal over

1 bus 30 to the respective slave CMTS devices 24. At step 60, the respective slave CMTS devices
24 receive the control signal and process same to determine that the stored time stamp value must
be retrieved. Each slave CMTS device 24 then retrieves the time stamp value from its load
register or other suitable location, and loads its counter with that value. Operation then
5 terminates at step 62.

In this manner, the CMTS devices 22 and 24 are all synchronized to the same time stamp
value, which provides system redundancy. If one of the CMTS devices 24 fails, one or more of
the other devices 24 can assume the failed device's load and process requests from the cable
modems 12 that were previously being serviced by the now-unavailable device 24. As is well
10 known in the art, cable modem systems are very dependent on timing information. If two of the
CMTS devices are slightly off in terms of timing, one CMTS device cannot assume the other
CMTS device's load without causing the associated cable modems to be affected. Thus, by
providing multiple, synchronized CMTS devices, the respective cable modems can be serviced
by any of those devices. Thus, system 20 can engage in load balancing and can send commands
15 to transfer the cable modems 12 between the respective downstream channels 26.

Preferably, the synchronization method of FIG. 4 is frequently repeated to continually
ensure that the various CMTS devices 22 and 24 remain synchronized with one another. The
frequency of performing the method depends on the precision of the reference oscillators used.
In one illustrative embodiment, each of the CMTS devices 22 and 24 includes its own reference
20 oscillator having a precision on the order of 50 parts per million ("PPM"), in which case a future
time stamp value is transmitted on the order of once per millisecond. However, it will be
apparent to those skilled in the art that the rate at which the synchronization process is performed
will vary depending on many factors, including the system timebase quality. For example, if the
reference oscillators are of very high quality, the synchronization process of FIG. 4 may be
25 performed less frequently. In addition, in an alternative embodiment described in more detail
below, the same timebase may be used for all slave devices and the master device, in which case
the synchronization process may be repeated relatively infrequently, if at all.

According to another aspect of the invention, system 20 also controls the sharing of MAP
information among the respective CMTS devices 22 and 24 of system 20. MAP information is
30 generated by a component of system 20 (e.g., CPU 311), with time slots then being allocated to
the respective cable modems, dictating when those cable modems may transmit messages over
one of the upstream channels. That time slot information is then transmitted to the cable modems
over the respective downstream channels.

According to one illustrative embodiment of the invention, a method is provided for
35 sharing upstream MAP information amongst the respective CMTS devices 22 and 24. As
described above, each CMTS device 22 and 24 is connected to at least one upstream channel 28.
Each of these channels is assigned a unique identifier that is recognized by the component
assigning the time slots, as well as by the respective CMTS devices 22 and 24.

Operation of the MAP sharing method begins at step 100, with system 20 assigning time

1 slots for each upstream channel 28, and generating corresponding MAP information, along with
channel identification information for each time slot. For example, time slot number one on
upstream channel number one may be assigned to cable modem X, while time slot two on
channel number one is assigned to cable modem Y. In addition, time slot number one on
5 upstream channel number two is assigned to cable modem Z, while time slot number two on
channel number two is assigned to cable modem W. Thus, each discrete time slot assignment
preferably is a data block that includes information to identify 1) the time slot, 2) the upstream
channel, and 3) the cable modem. In one illustrative embodiment, such functionality is carried
out by CPU 311.

10 At step 102, the MAP information is transmitted to the master CMTS device 22,
preferably over bus 30. Master CMTS device 22 then forwards the MAP information on to the
respective cable modems 12 over downstream channel 26, at step 104. The cable modems
receive the time slot information and store the relevant time slot information in a register until
the appropriate time, at which time the cable modems are allowed to transmit information to the
15 CMTS device over the respective upstream channels 28. At step 106, master CMTS device 22
broadcasts the MAP information to the slave CMTS devices 24.

At step 108, the respective slave CMTS devices 24 receive the MAP information and
analyze the channel identification information for the respective assignments. At query block
110, each CMTS device determines whether the channel identification information matches with
20 one of the channels connected to that CMTS device. If so, then operation proceeds to step 112,
and the corresponding assignment is stored by that CMTS device.

On the other hand, if the channel identification information does not match with one of
the channels connected to a particular CMTS device, then operation proceeds to step 114 and that
MAP information is ignored by that particular CMTS device. In that manner, each slave CMTS
25 device 24 only stores the MAP information relevant to it. The irrelevant information is
discarded.

Alternatively, the MAP information may be simultaneously broadcast to each of the
CMTS devices 22 and 24, with master device 22 forwarding the MAP information on to the cable
modems 12, and each CMTS device 22 and 24 then filtering the MAP information and storing
30 the relevant information for the respective CMTS device. In yet another embodiment, the MAP
information may be transmitted to each CMTS device 22 and 24 that has an associated
downstream channel 26, so that the MAP information can be transmitted to all of the cable
modems 12. One of those CMTS devices (for example, the master device 22) then broadcasts
the MAP information to the other slave devices 24, and the filtering step is then carried out.

35 As described above, a number of different control bits are transmitted over bus 30 by
master CMTS device 22 and by other components of system 20, along with the MAP information
and future time stamp value information. The control data includes data to indicate the type of
data being transmitted (either MAP or time stamp value information), control data to alert the
slave CMTS devices 24 that a time stamp value is then valid, and end-of-package (EOP) control

1 data to indicate the end of a block of MAP information.

It will be understood by those skilled in the art that the future time stamp value must be transmitted some amount of time before the master device's internal counter reaches the time stamp value. In one illustrative embodiment, the future time stamp value is transmitted between
5 about 8 and about 64 synchronization clock cycles prior to reaching the future value, so as to ensure that the slave devices 24 receive the time stamp value in a timely manner.

In one embodiment described above, each of the master and slave CMTS devices 22 and 24 includes its own reference oscillator. Depending on the precision of those oscillators, the synchronization process will have to be repeated more or less often. For example, in the case of
10 oscillators with a precision of 50 PPM, it is desirable to repeat the process once per millisecond.

Alternatively, the respective CMTS devices 22 and 24 can be driven from a single reference oscillator, in which case the respective counters in each CMTS device need not be updated as frequently, if at all. This allows for setting the counter value once, with only periodic checks being done to ensure that the slave devices 24 remain synchronized with the master device
15 22. In this alternate embodiment, because each of the master and slave devices 22 and 24 are run from the same oscillator, it is presumed that the respective devices 22 and 24 remain in synchronization with each other for relatively long periods of time. Thus, the initial synchronization process is identical to that described above in connection with FIG. 4. However, the synchronization process shown in FIG. 4 need not be frequently repeated. Rather, CPU 311
20 is preferably programmed to periodically read the value in TGCVerify register 306 from one or more of the slave devices 24 and to compare that value with the value in register 306 of master device 22. If the two values are not identical, then the process of FIG. 4 may be repeated to regain synchronization.

Referring now to FIG. 6, there is shown a schematic of a circuit 200 that may be
25 incorporated into each CMTS device 22 and 24 for performing the time-stamp generation and time-stamp synchronization functions. The circuit 200 includes a counter 202 including an accumulator 204, a pair of multiplexers (MUX) 206 and 207, and thirty two D-type flip flops 208 (shown schematically) to process the individual bits of a 32-bit time stamp. The accumulator 204 increments the output of the flip flops 208 (i.e., the time stamp value of the counter 202), and
30 introduces the incremented value to MUX 206, which also receives the time stamp value from flip flops 208 directly. MUX 206 is designed to select the output from flip flops 208 until it is triggered by a rising edge of TikClk introduced to MUX 206, in which case the signal from accumulator 204 is selected. The output of MUX 206 is introduced to MUX 207, along with a TSLoadVal signal from a TSLoadVal Register 304 (FIG. 7). MUX 207 is designed to select the
35 output from MUX 206 until it receives a ld_ts signal pulse, in which case MUX 207 is designed to select the TSLoadVal signal and to output same. The output of MUX 207 is introduced to the D inputs of the respective 32 flip flops 208 (one bit per flip flop), which serve to update the value of the local counter upon the next rising edge of the clock input.

The output of the counter 202 is introduced to a pair of multiplexers 210 and 212. The

1 output of each MUX 210 and 212 is introduced to the D inputs of respective D-type flip flops 214 and 216, and the Q outputs of each flip flop 214 and 216 define, respectively, TSRegister (TSR) and TGCVerify (TGCV) signals, which are fed back to the respective MUXs 210 and 212. Thus, each MUX 210 and 212 is designed to select the output from the corresponding flip flop 214 and
5 216 (i.e., the output of each flip flop remains static) until the MUXs receive respective trigger signal VerTGC and TSLatch, as is described in more detail below. When either MUX 210 or 212 receives the corresponding trigger signal, the current counter value TGC (i.e., the output of flip flops 208) is selected by that MUX, and is passed on through the corresponding flip flop as output signal TGCV or TSR.

10 Circuit 200 also includes a synchronizer 220 consisting of a plurality of D-type flip flops 222, 224, 226, and 228 arranged in series. Each flip flop preferably receives the 20.48 MHz clock. The first flip flop 222 receives a TSSync pulse at its D input, and has its Q output coupled to the D input of flip flop 224. The Q output of flip flop 224 is coupled to the D input of flip flop 226, and is also coupled to one input of an AND gate 230. The output of flip flop 226 is coupled
15 to an inverted input of AND gate 230. Thus, when the Q output from flip flop 224 goes high, the output of AND gate 230 goes high, which triggers flip flop 228 to generate the TSLatch pulse at its Q output, which is introduced to MUX 210.

Thus, the synchronizer 220 may be used to perform a synchronization technique in which a register may be loaded by logic that uses one clock domain (e.g., 20.48 MHz), and the register
20 may then be read by logic that uses a different clock domain (e.g., 100 MHz). This allows for moving the counter time stamp value from the 20.48 MHz time domain of the circuit 200 into the 100 MHz time domain of the overall system clock. The synchronizer 220 receives the TSSync pulse that is generated on the system clock (e.g., 100 MHz), and outputs the TSLatch pulse that is on the TGC time base (e.g., 20.48 MHz). The TSSync pulse preferably has a width
25 greater than one clock cycle of the TGC time base. The TSSync pulse is synchronized by the synchronizer 220, which is driven by the TGC clock (e.g., 20.48 MHz). Thus, the TSSync pulse is generated by the timebase which drives the logic that will read the contents of the register.

Preferably, the TSSync pulse is generated a predetermined amount of time prior to the actual read of the contents of the register, and synchronized to provide a rising edge detection by
30 logic driven by the same timebase which also drives the logic that loads the contents of the register.

Circuit 200 also includes D-type flip flop 232, which serves to divide the frequency of the 20.48 MHz clock by a factor of two, and supplies the inverted 10.24 MHz TikClk signal to MUX 206. As shown in FIG. 8, the TikClk is $\frac{1}{2}$ the 20.48 MHz reference oscillator and is
35 centered $\frac{1}{2}$ way between TGC transitions. This allows the rising edge of the 10.24 MHz TikClk signal to be exactly centered within the TGC value.

Referring now to FIG. 7, a circuit 300 is shown in block diagram form, which includes circuit 200 and additional components. Circuit 300 includes a comparison register TGCCompReg 302, a future time stamp register TSLoadValReg 304, the time stamp generation

1 counter (TGC) 202, a verify register TGCVerify 306, and a time stamp register TSRegister 308. Circuit 300 communicates with the system 20 via a DS host interface 309. Circuit 300 may be used in either the master CMTS device 22, or in the slave CMTS devices 24, as is described in detail below.

5 TGCCompReg 302 serves to hold the future time stamp value for the master CMTS device 22, while TSLoadValReg 304 holds the future time stamp value for each slave CMTS device 24. Each register 302 and 304 receives a TSLoadVal signal from the component generating the future time stamp values, as is described in more detail below.

10 As described above, the TGC counters 202 serve to continually update the current time stamp value for the corresponding CMTS devices. In the master device 22, the continually incrementing output of the counter 202 is introduced to AND gate 310, along with the value in the TGCCompReg 302. When the value in register 302 matches the value in counter 202, a pulse is generated by AND gate 310 which is introduced to the D input of a D-type flip flop 312, whose Q output then generates a load signal LdTsExt, which is broadcast to each of the slave CMTS
15 devices 24.

Each slave CMTS device 24 receives the LdTsExt signal at an OR gate 314, along with a register command LdTsInt, either of which causes the output of OR gate 314 to go high. The output from the OR gate is introduced to synchronizer 316, which generates the ld_ts signal at the next rising edge of the 20.48 MHz clock signal. The ld_ts signal is introduced to counter 202,
20 which is thereby triggered to retrieve the future time stamp value from register 304 and to set the value of counter 202 to that value to thereby synchronize each slave CMTS device 24 with master CMTS device 22.

The value of counter 202 is also introduced to registers 306 and 308 in response to receipt of the TGCV and TSR signals from respective flip flops 210 and 212 (FIG. 6). The values in
25 each register 306 and 308 can be verified by respective VerTGC and VerTSR signals received via DS host interface 309.

System 20 includes appropriate software for generating the future time stamp value, with such software controlling an appropriate component of system 20, such as CPU 311. In one embodiment, the CPU 311 is controlled by software to poll the counter 202 of master CMTS
30 device 22 for the current time stamp value. Thus, an appropriate polling signal is transmitted and received by the host interface 309. The signal is passed to a synchronizer 320, which outputs VerTGC signal on the next rising edge of the 20.48 MHz clock. The VerTGC signal is received by MUX 212 (FIG. 6), which then passes the current time stamp value to TGCVerify register 306, which in turn passes the time stamp value to the CPU 311 through interface 309.

35 The software then controls CPU 311 to take the current time stamp value, add some predetermined number of cycles to that value to generate the future time stamp value, and to pass the signal on to the respective CMTS devices 22 and 24 as TSLoadVal, which is received by the respective registers 302 and 304. Then, as described above, when the value in register 302 equals the counter value, the LdTsExt pulse is generated by the master CMTS device 22. Each slave

1 receives the pulse at OR gate 314, forwards the pulse as signal `ld_ts` to counter 202 of each slave device 24, which then takes the value in register 304 and loads that value into counter 202, to thereby synchronize the respective devices 22 and 24.

5 Because the `LdTsExt` pulse passes through synchronizer 316 and the output from AND gate 310 passes through flip flop 312 before updating the counters 202 in the slave devices 24, the slave devices 24 may be one or two clock cycles behind the master device 22 once their counters 202 are updated. Thus, in one embodiment, the value transmitted to the `TGCCompReg` register 302 is deliberately selected to be one or two cycles behind the value transmitted to the `TSLoadVal` registers 304 of each slave device 24. In this manner, by the time the counters in the
10 slave devices 24 have been updated, the time stamp of the master device 22 will have advanced one or two cycles, and the devices 22 and 24 will be synchronized.

In another embodiment, the registers 302 and 304 are combined into a single register, used for both comparison purposes in the master device 22 and for holding the future time stamp value and updating the counter 202 in the respective slave devices 24. In that embodiment, the
15 output from AND gate 310 in master device 22 serves as the `LdTsExt` pulse signal, and is connected directly to the respective registers in the slave devices 24 to immediately cause the counters 202 in the slave devices 24 to be updated to the new time stamp value.

Referring now to FIG. 8, there is shown the timing relationships and clock domain properties for the loading, transfer, and verification of TGC values. In the illustrative
20 embodiment shown, the TGC clock runs at 20.48 MHz, while the system clock `Sys_Clk` is at 100 MHz.

Still referring to FIG. 8, when a time-stamped message is to be sent downstream to the cable modems 12, a `TSSync` pulse is generated on a byte number that is a predetermined number of bytes prior to the location of the actual time stamp. The `TSSync` pulse is synchronized by edge
25 detection into the 20.48 MHz domain. The resulting `TSLatch` pulse serves to capture the current TGC value and has that value available in `TSRegister` 308 a predetermined amount of time before it is needed for insertion into the downstream time-stamped message.

The `TSLatch` pulse triggers MUX 210, such that the next rising edge of the clock causes the value of `TSRegister` 308 to be updated with the then-current value of counter 202. The value
30 of `TSRegister` 308 then remains fixed until the next `TSLatch` pulse is received by MUX 210.

This invention is used in a CMTS device disclosed in an application entitled "Method and Apparatus for the Reduction of Upstream Request Processing Latency in a Cable Modem Termination System" Serial No. _____, (Attorney docket B600:36885) filed on even
35 date herewith by Lisa Denney, Angers Hebsgaard, and Robert J. Lee, the disclosure of which is incorporated fully herein by reference.

From the foregoing, it will be apparent to those skilled in the art that the present invention provides a system and method for maintaining synchronization between multiple CMTS devices. In addition, the invention allows for the sharing of MAP information between the multiple CMTS devices.

1 While the above description contains many specific features of the invention, these should
not be construed as limitations on the scope of the invention, but rather as exemplary
embodiments thereof. Many other variations are possible. Accordingly, the scope of the
invention should be determined not by the embodiments illustrated, but by the appended claims
5 and their legal equivalents.

1 What is claimed is:

1. A system for synchronizing plural cable modem termination devices, comprising:
a master cable modem termination system device, said device having at least one
downstream channel and at least one upstream channel for communicating with plural cable
5 modems, said master device further including a counter;

plural slave cable modem termination system devices connected to the master cable
modem termination system device, wherein each slave device has at least one upstream channel
for receiving communications from plural cable modems, each slave device further including a
counter;

10 a processor programmed to calculate a future time stamp value and to transmit said value
to each of the master and slave devices;

wherein the master device is designed to compare the future time stamp value with the
value of the counter, and to transmit a signal to each slave device when the counter of the master
device and the future time stamp have equal values, the slave devices being operative in response
15 to said signal to load the future time stamp value to the respective counters.

2. The system of claim 1, wherein the processor is programmed to calculate a future
time stamp value for the master device and a different future time stamp value for the slave
devices, where the values are offset by a predetermined number of clock cycles.

20 3. The system of claim 1, wherein the processor is programmed to query the master
device for its current time stamp value, and to calculate the future time stamp value based on the
current time stamp value of the master device.

25 4. The system of claim 1, wherein the processor is programmed to transmit the future
time stamp value a predetermined amount of time prior to reaching the future time stamp value.

30 5. The system of claim 4, wherein the processor is programmed to transmit the future
time stamp value between about eight and about 64 clock cycles prior to reaching the future time
stamp value.

6. The system of claim 1, wherein the processor is programmed to generate a new
future time stamp value once every predetermined amount of time.

35 7. The system of claim 6, wherein the processor is programmed to generate a new
future time stamp value once per millisecond.

8. The system of claim 1, wherein the processor is included in the master CMTS
device.

1 9. The system of claim 1, further including a register that is used to store a current time stamp value, and means for storing data to the register using a first clock domain, and means for reading the data from the register using a second clock domain.

5 10. A method of synchronizing plural cable modem termination system (CMTS) devices, comprising:
 generating a future time stamp value;
 transmitting the future time stamp value to a master CMTS device and to plural slave CMTS devices;
10 storing the future time stamp value at each device;
 comparing the future time stamp value with a current time stamp value at the master device;
 generating a signal at the master device when the future time stamp value matches the current time stamp value;
15 transmitting the signal to the respective slave devices;
 at each slave device, setting a local counter to the future time stamp value upon receipt of the signal.

20 11. The method of claim 10, wherein transmitting the command signal to the respective slave devices comprises broadcasting the command signal over a bus.

25 12. The method of claim 10, wherein transmitting the future time stamp value comprises transmitting the value a predetermined number of cycles prior to reaching the future time stamp value.

 13. The method of claim 10, wherein transmitting the future time stamp value comprises transmitting the value between about eight and about 64 cycles prior to reaching the future time stamp value.

30 14. The method of claim 10, wherein generating the future time stamp value occurs once per predetermined period.

 15. The method of claim 10, wherein generating the future time stamp value occurs once per millisecond.

35 16. The method of claim 10, further including storing a time stamp value to a register using a first clock domain, and reading the time stamp value from the register using a second clock domain.

1 17. A method of allocating time slots on a plurality of upstream channels, wherein there are multiple cable modem termination system (CMTS) devices, with each CMTS device being connected to at least one upstream channel, the method comprising:

 assigning a unique identifier to each of the channels;

5 generating time-slot allocation information for the respective channels;

 transmitting the allocation information to at least one of the CMTS devices;

 forwarding the allocation information to plural cable modems over a downstream channel;

 transmitting the allocation information to the remainder of the CMTS devices;

10 at each CMTS device, determining whether the allocation information pertains to an upstream channel associated with that CMTS device; and

 at each CMTS device, retrieving the allocation information if the allocation information pertains to an upstream channel associated with that CMTS device.

15 18. The method of claim 17, wherein the generated time-slot information includes time slot allocations, channel identification information, and cable modem identification information.

20 19. The method of claim 17, wherein determining whether the allocation information pertains to that CMTS device comprises processing the allocation information to compare channel identification information with the one or more channels connected to that CMTS device.

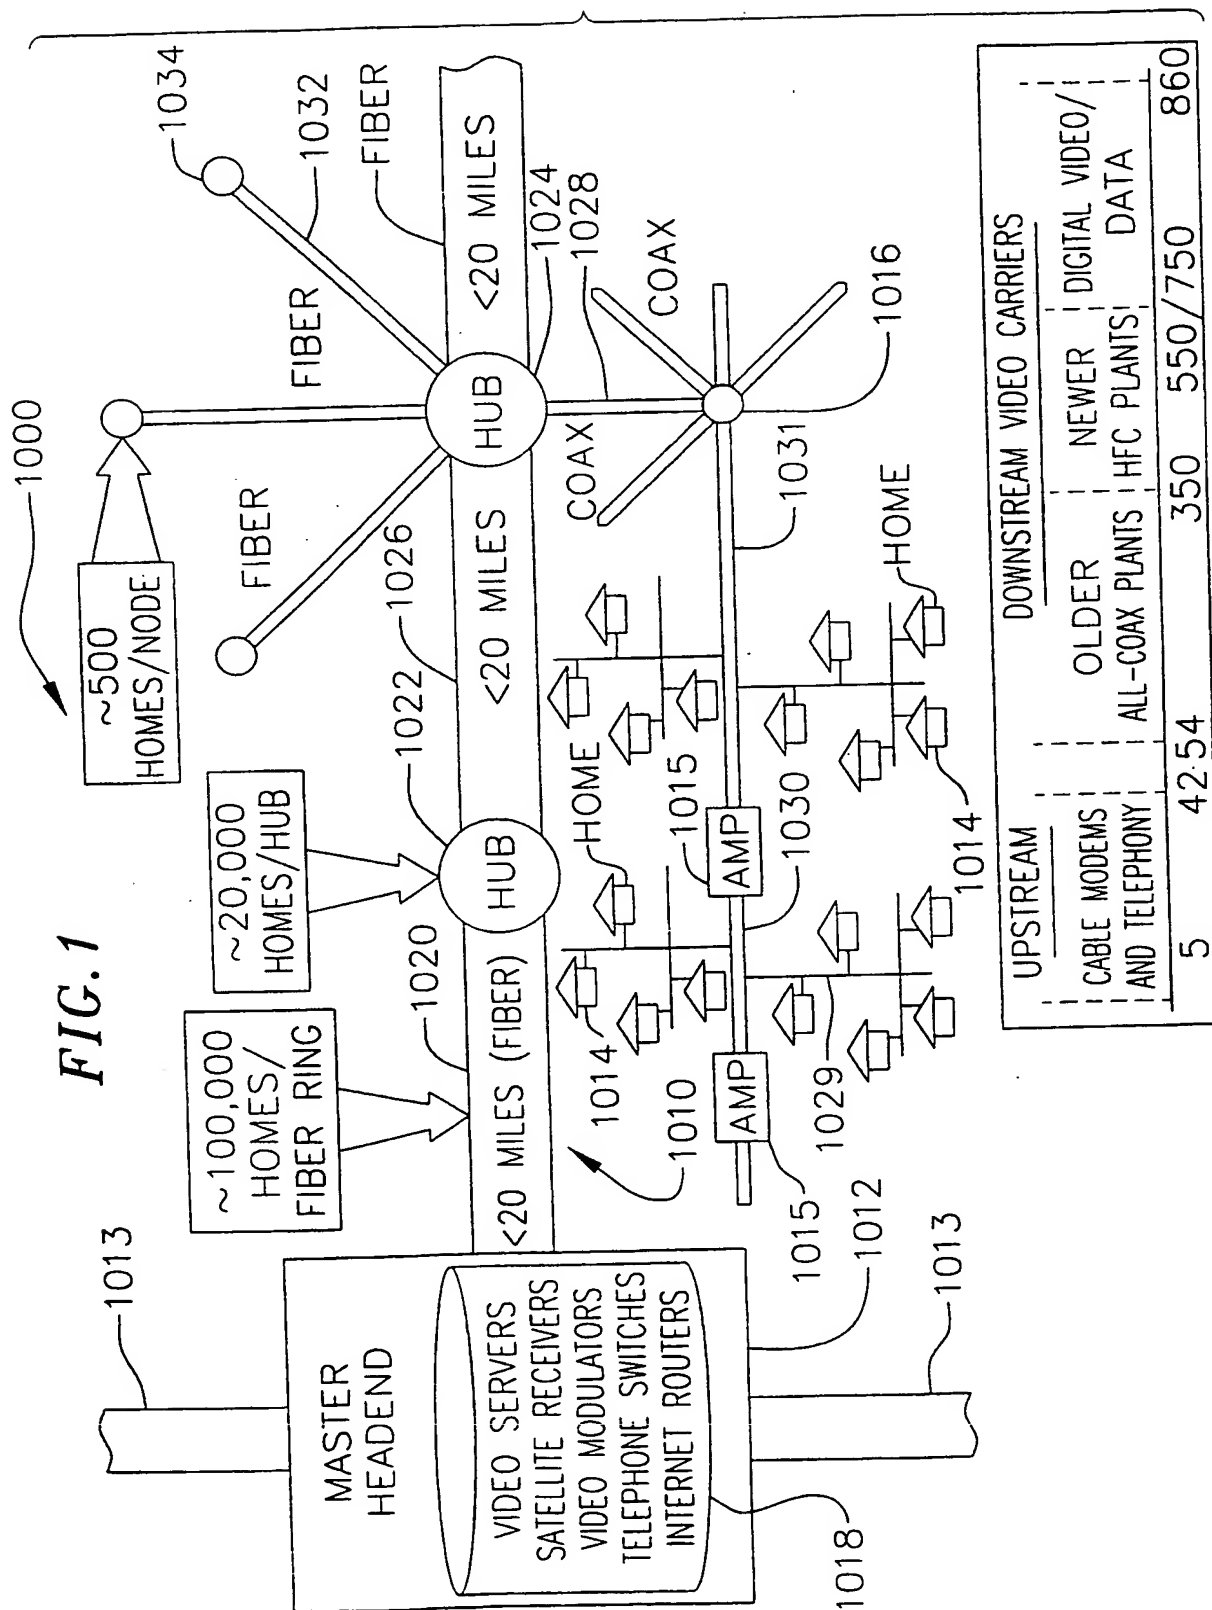

25 20. The method of claim 17, wherein retrieving comprises retrieving the allocation information if channel identification information in the allocation information matches with an identifier of a channel connected to that CMTS device.

 21. The method of claim 17, wherein transmitting comprises transmitting the allocation information to a master CMTS device.

30 22. The method of claim 21, wherein transmitting the allocation information to the remainder of the CMTS devices comprises broadcasting the allocation information from the master CMTS device to the other CMTS devices over a bus.

35 23. The method of claim 17, wherein transmitting the allocation information to at least one of the CMTS devices comprises transmitting to each CMTS device.

 24. The method of claim 17, wherein transmitting the allocation information to at least one of the CMTS devices comprises transmitting allocation information to each CMTS device having a corresponding downstream channel.

(54) Title: **METHOD AND APPARATUS FOR THE SYNCHRONIZATION OF MULTIPLE CABLE MODEM TERMINATION SYSTEM DEVICES**

(57) Abstract: A plurality of CMTS devices are linked together and synchronized to facilitate communication between the respective CMTS devices and respective downstream cable modems. According to one embodiment of the invention, one of the CMTS devices is designated as a master device, and the other CMTS devices are designated as slave devices. The respective CMTS devices are connected to each other by means of a synchronization bus. The master CMTS device then generates and broadcasts a future time stamp value, which is received by the respective slave CMTS devices. When the time stamp counter in the master CMTS device reaches the transmitted value, a control signal is broadcast over the synchronization bus. The slave CMTS devices then retrieve the time stamp value and reset their respective local time stamp counters to the received value. In this manner, the CMTS devices are synchronized.
